Service Continuity Using UE-to-Network Relays

David Griffith, Wireless Networks Division

2nd Workshop on 5G Technologies for Tactical and First Responder Networks

7 October 2019

National Institute of Standards and Technology
U.S. Department of Commerce

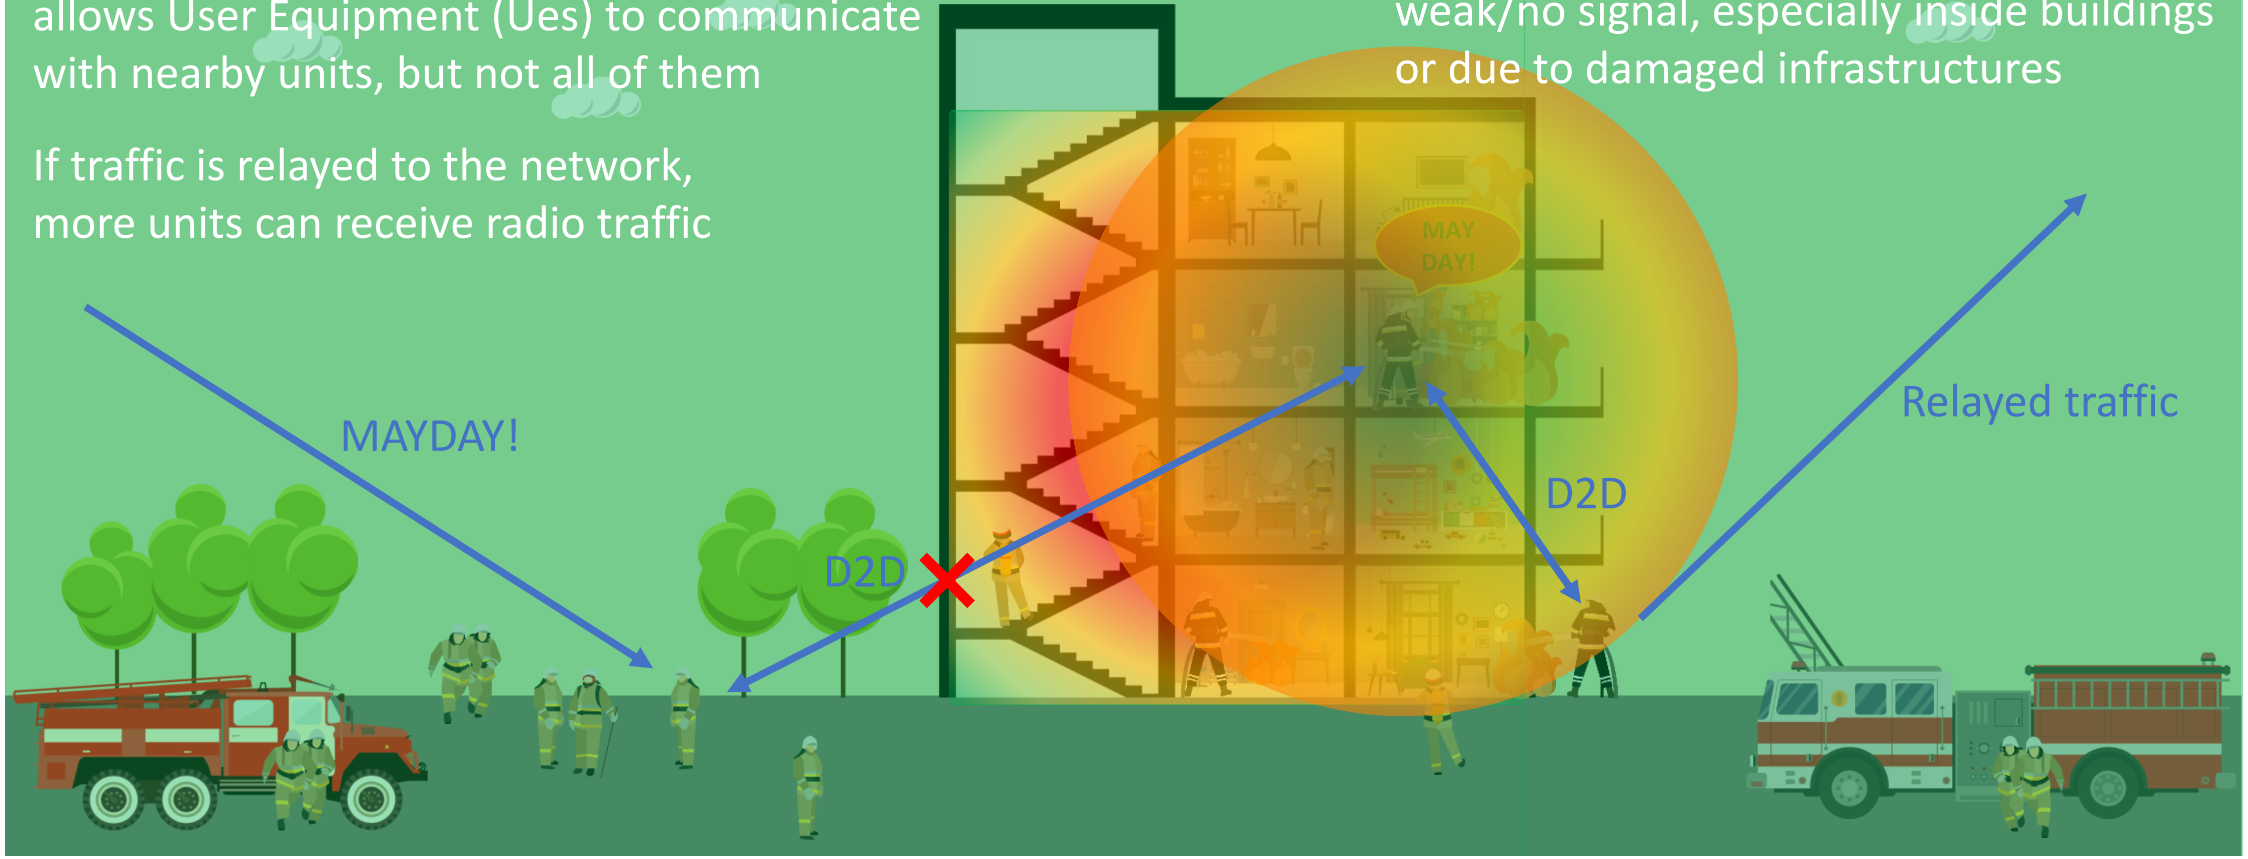
Communications Technology Laboratory

Partial Coverage Scenario

Device-to-Device (D2D) communication allows User Equipment (Ues) to communicate with nearby units, but not all of them

If traffic is relayed to the network, more units can receive radio traffic

Network coverage may contain areas of weak/no signal, especially inside buildings or due to damaged infrastructures



UE-to-Network Relay Functions

Relay Discovery and Selection

A UE losing connectivity with the network needs to discover the Relay UEs in proximity and select one to use

Relay Connection Establishment

The Remote UE exchanges signaling messages to establish a secure one-to-one link with the Relay UE

Relay Communication

The Relay UE does IP forwarding of packets between the network and the Remote UE

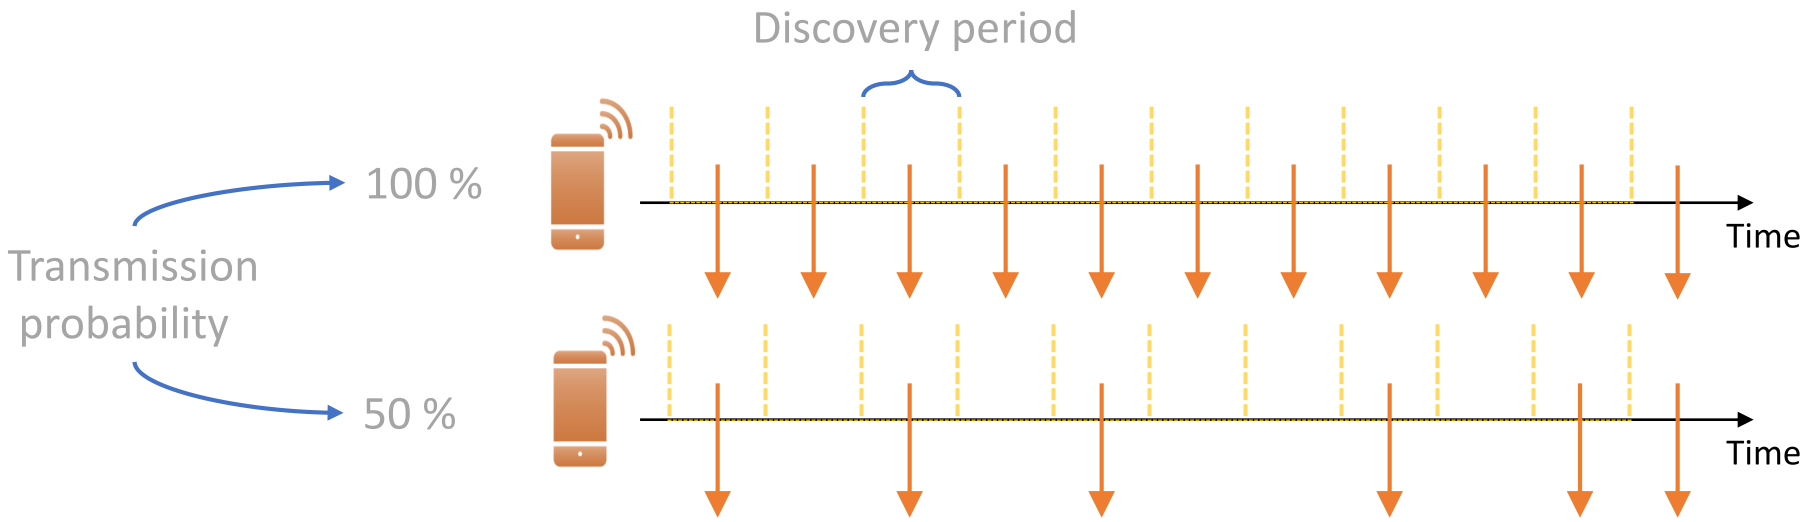
How long will the process take?
What is the impact on the user's experience?
What are the major factors impacting performance?

Relay Discovery and Selection

Which discovery method to use?
How many relays can be discovered?
Which relay to select?

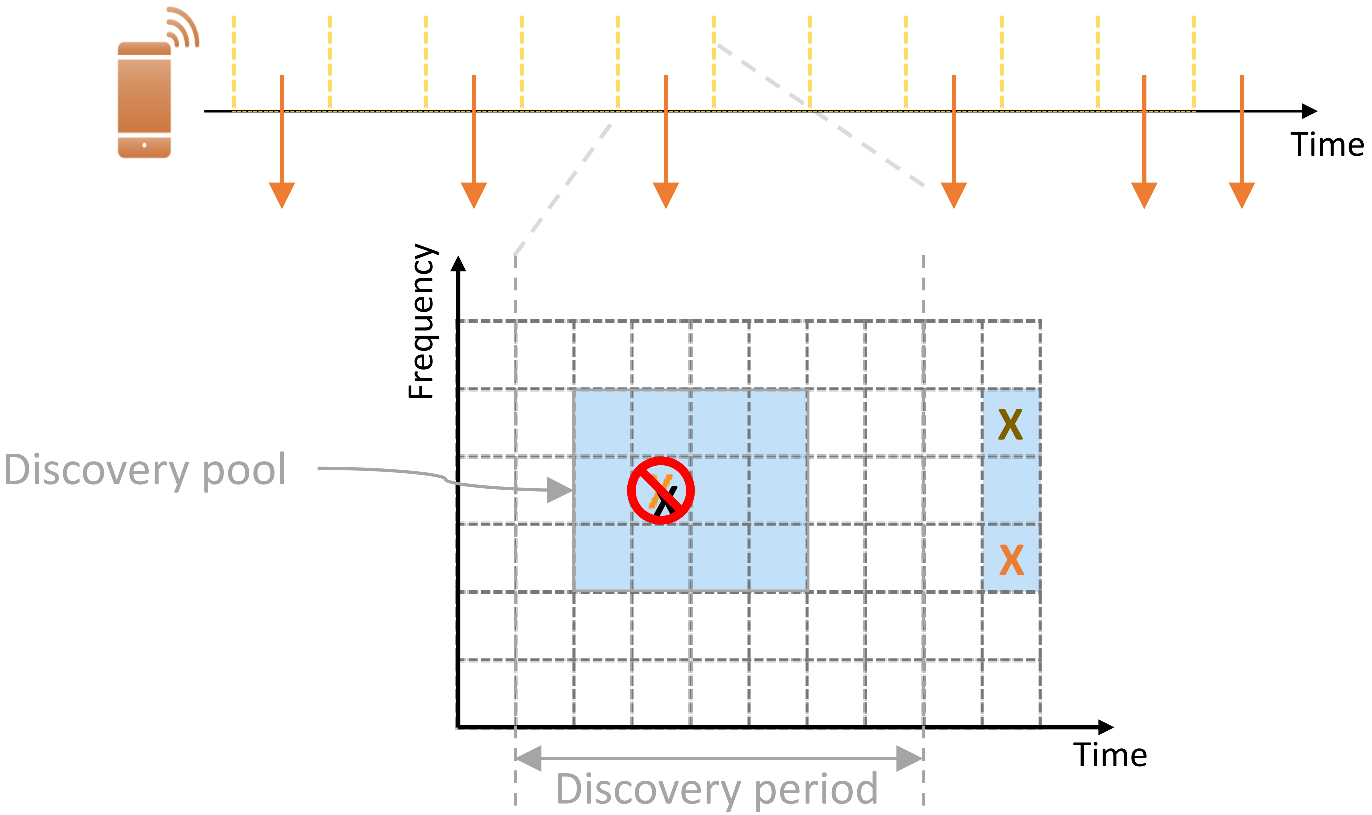
Relay Discovery Protocol Operation

- Discovery message transmission
  - Periodical (from 0.32 s up to 10.24 s)
  - Use transmission probability
  - Select resource randomly



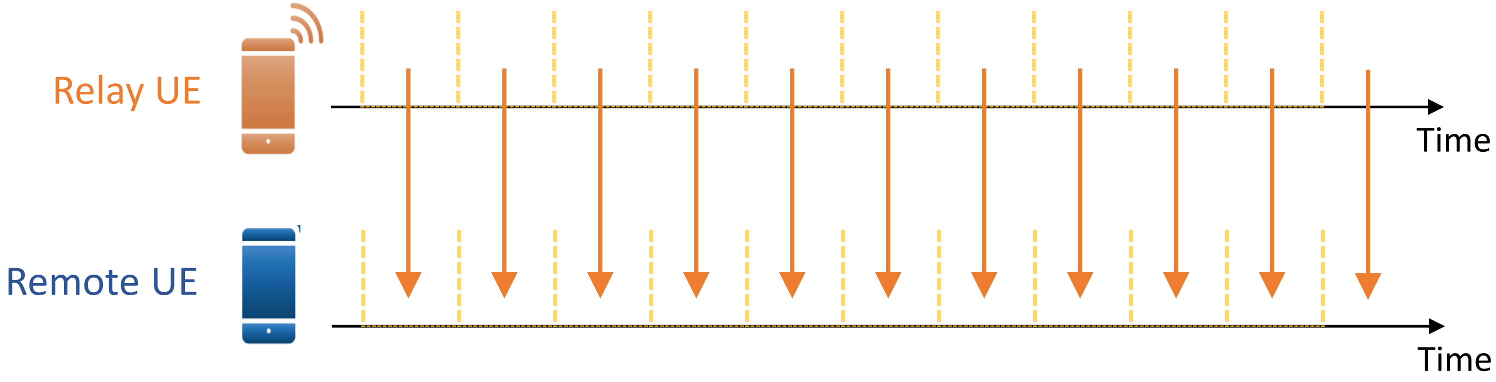
Relay Discovery Protocol Challenges

- Performance constraints / potential problems
  - Collisions
  - Half-duplex

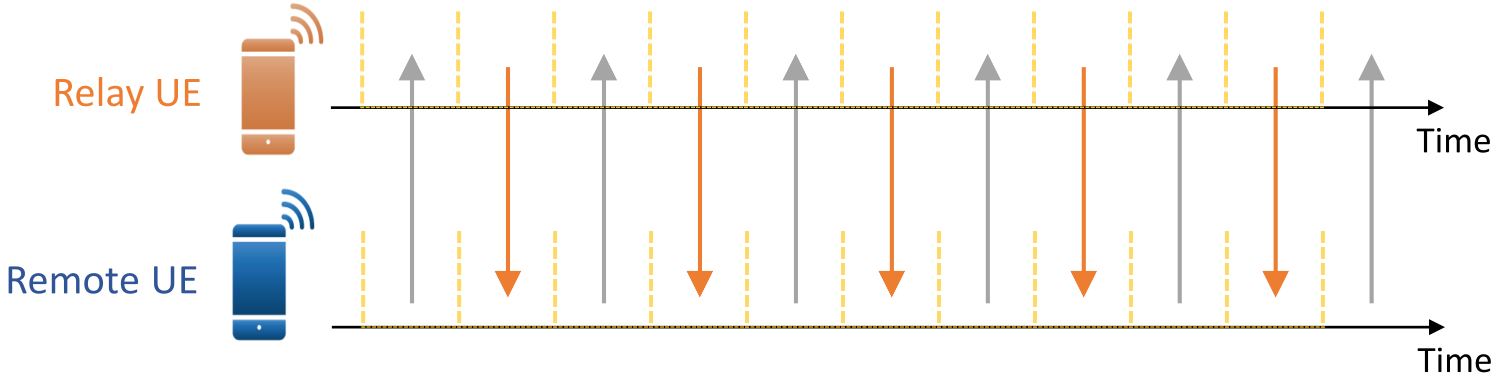


Relay Discovery Modes

Model A : Relay Announcement

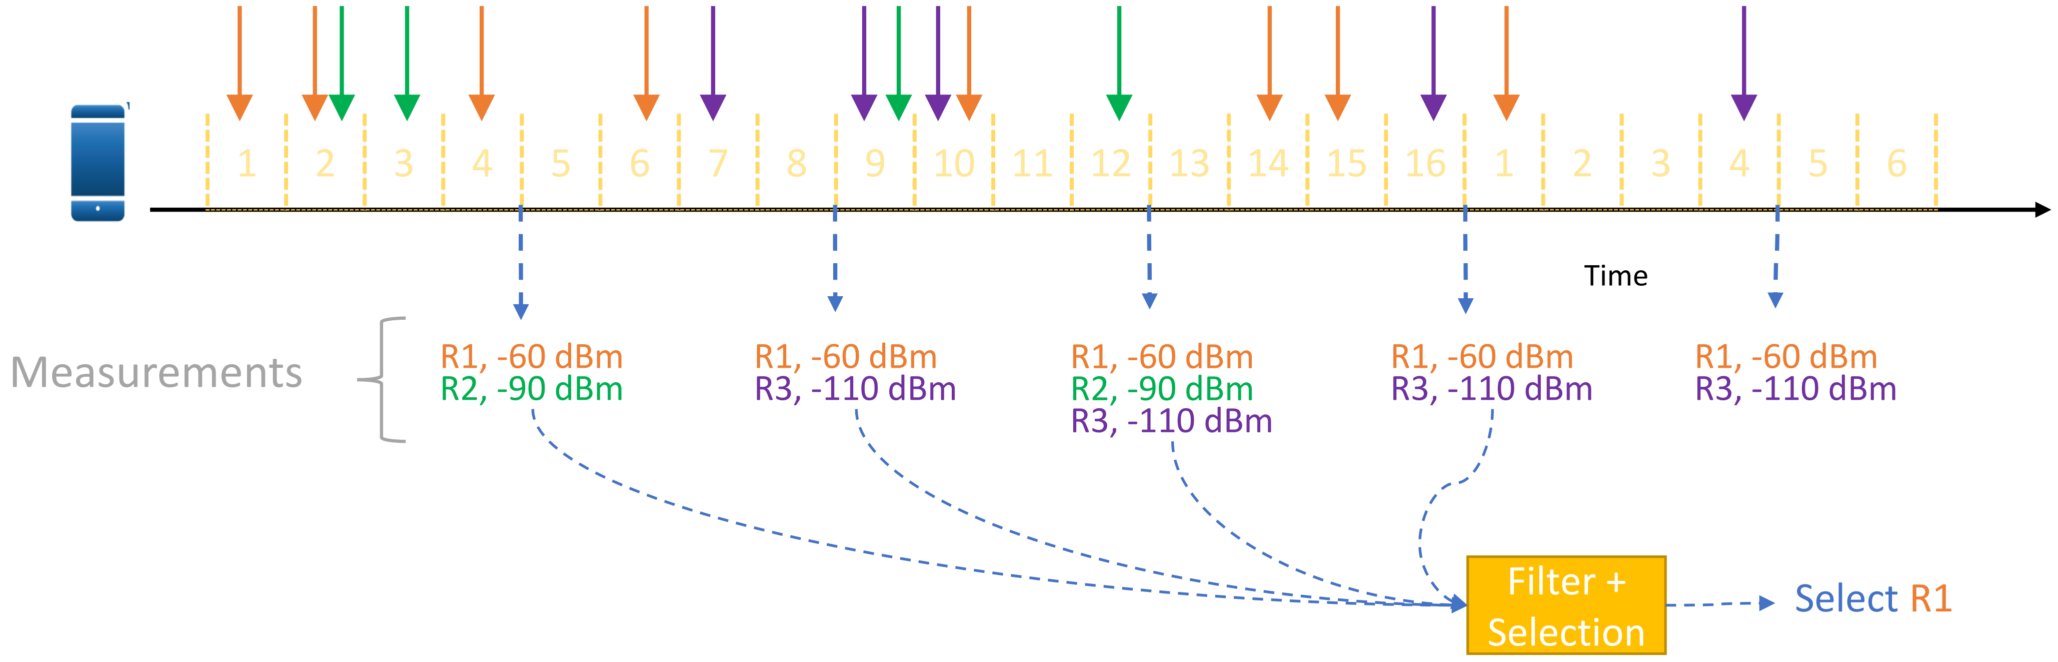


Model B : Relay Solicitation (Remote UE) - Relay Response (Relay UE)

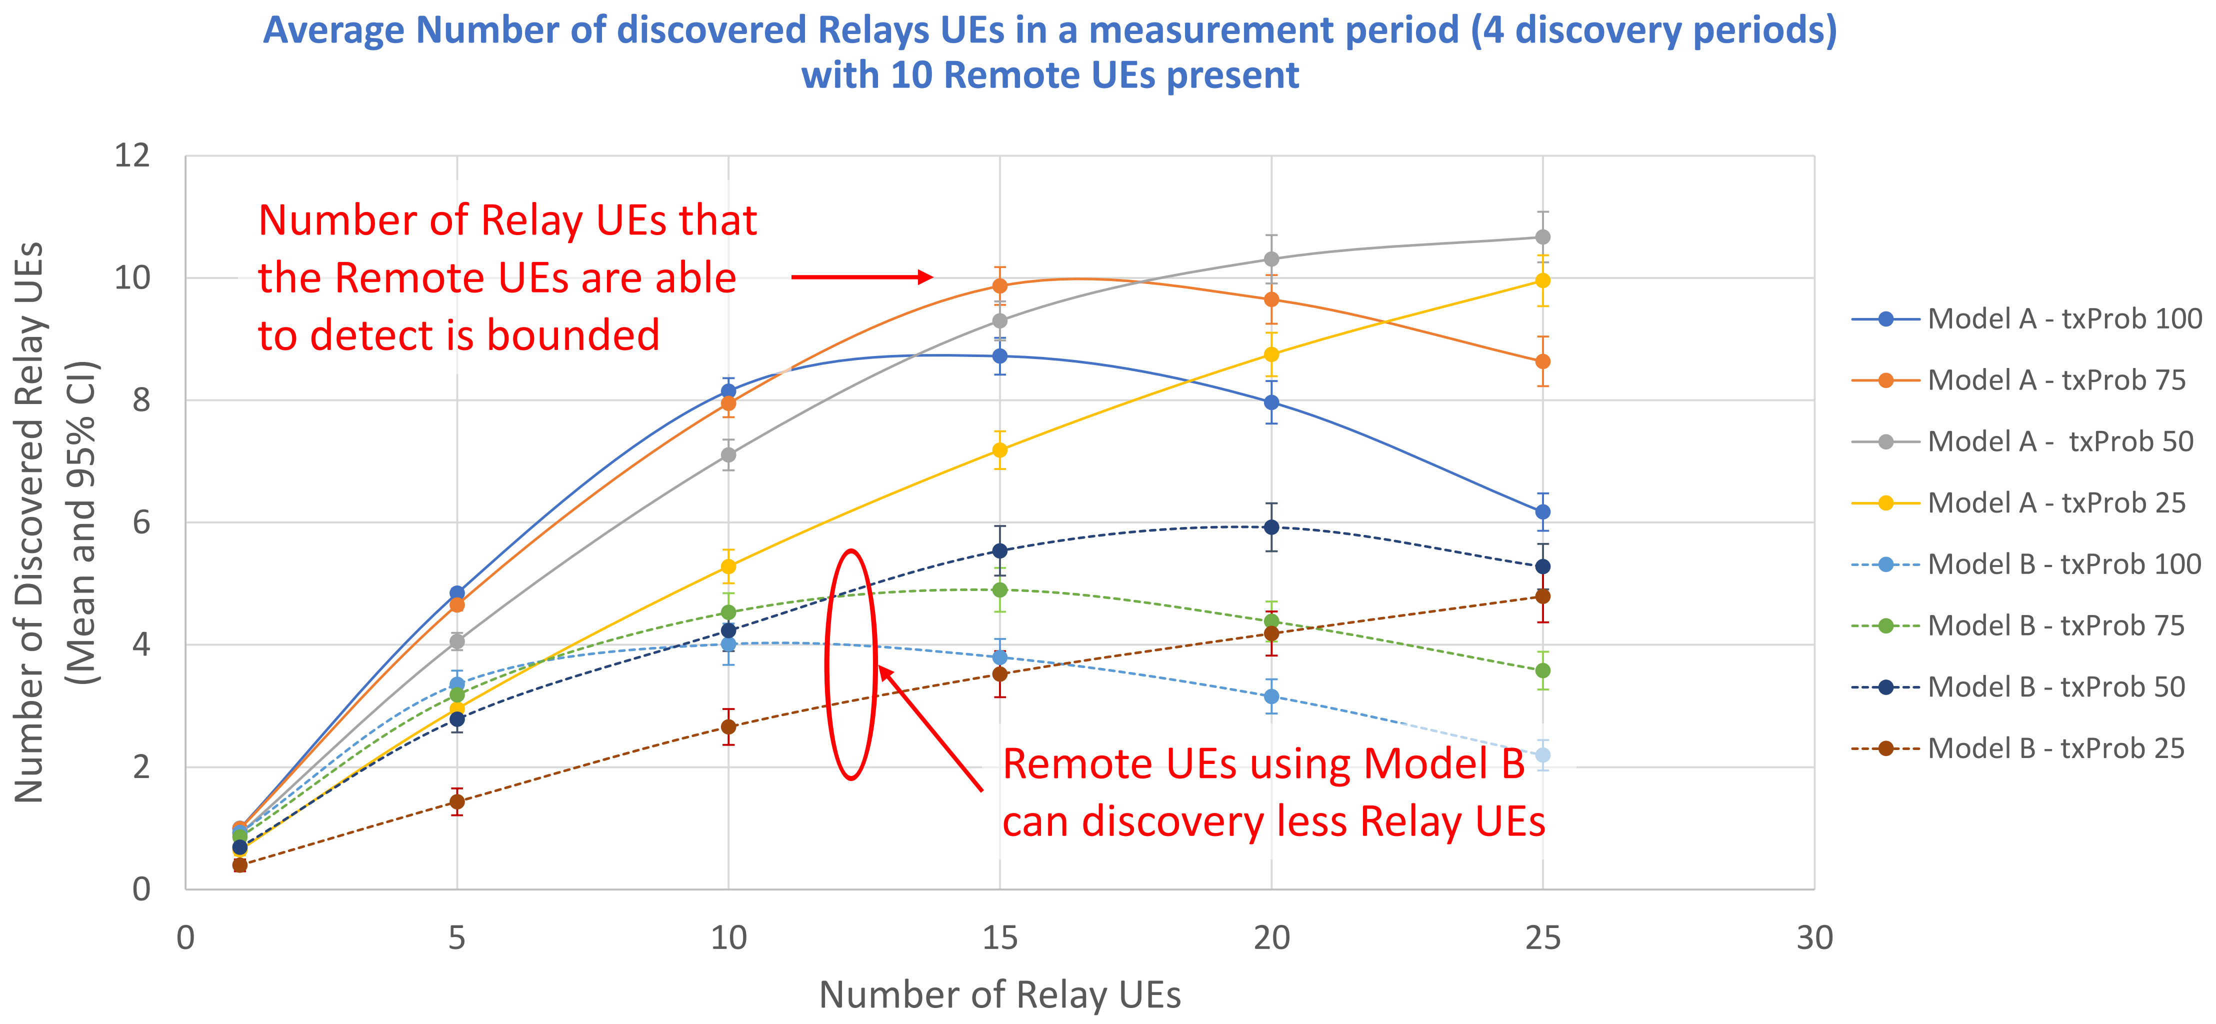


Relay Selection Process

- Search for candidate relay UEs every discovery period
- Measurement of the candidate relays every 4 discovery periods
- Evaluation of the candidate relays within 16 discovery periods

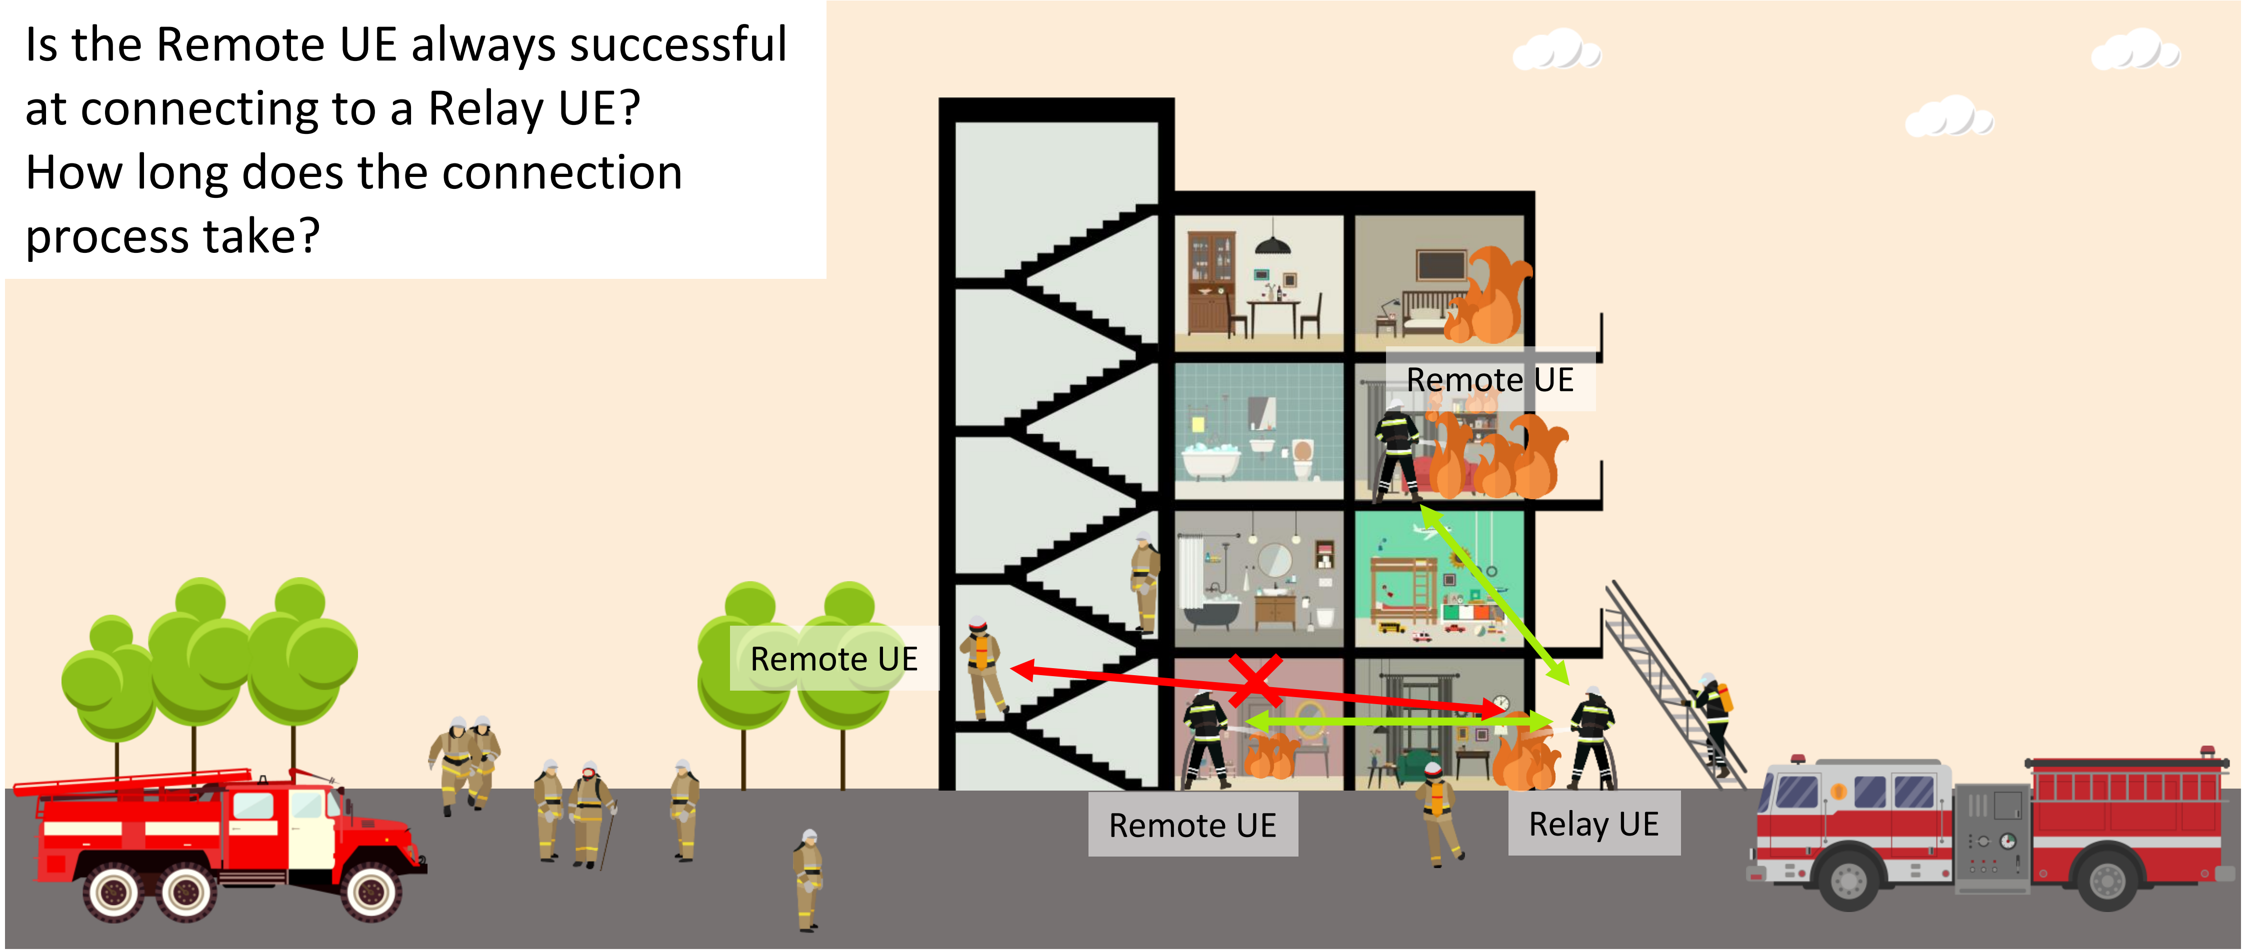


Impact of Discovery on Relay Selection



Relay Connection Establishment

Is the Remote UE always successful at connecting to a Relay UE?
How long does the connection process take?

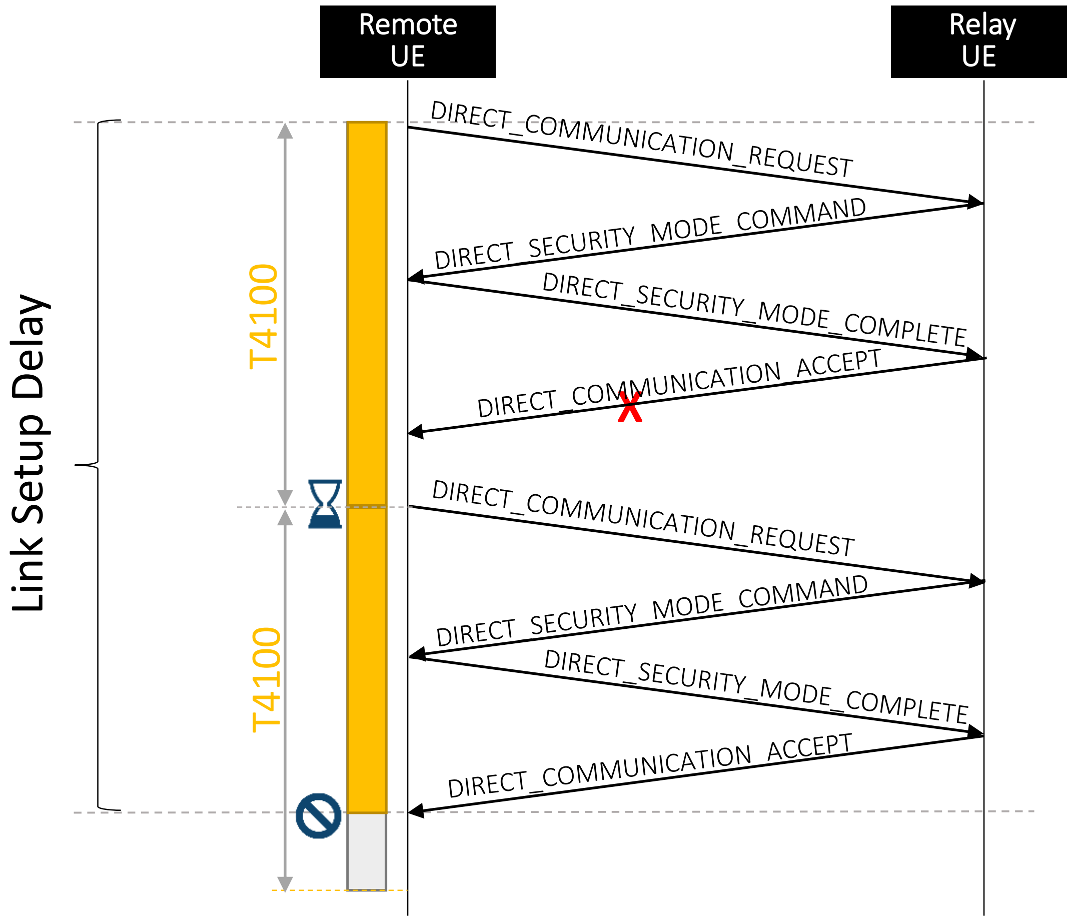


Relay Connection Establishment

- Direct Communication Link Setup requires signalling between the Remote UE and the Relay UE
- If messages are lost, recovery mechanisms are available based on the following parameters:
  - Duration of Direct Communication Request retransmission timer (T4100)
  - Maximum number of Direct Communication Request retransmissions upon expiration of T4100

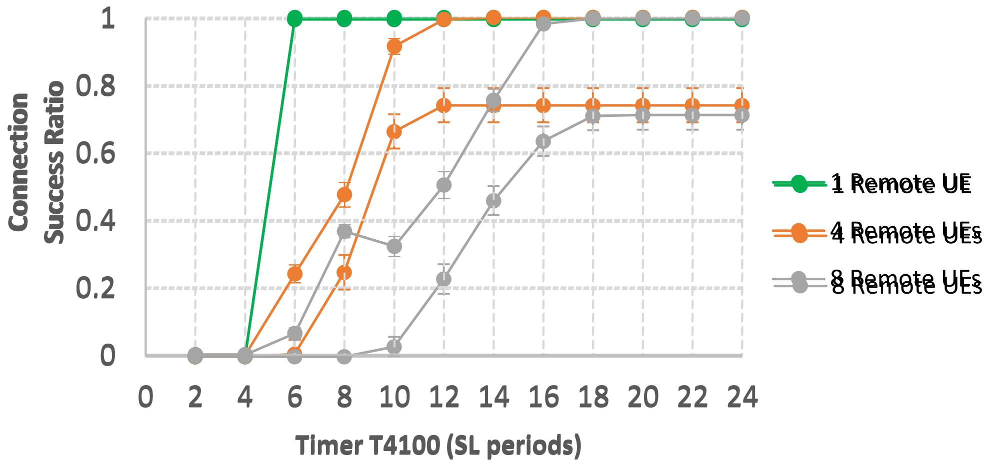
➔ How to configure those parameters?

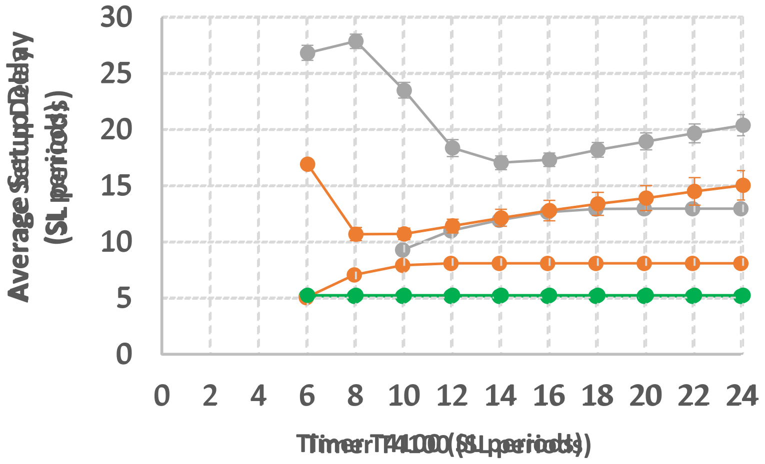
Direct Communication Link Setup Procedure



Impact of T4100 and Retransmissions

Up to 4 requests retransmissions / No requests retransmissions





Results with no background UL traffic

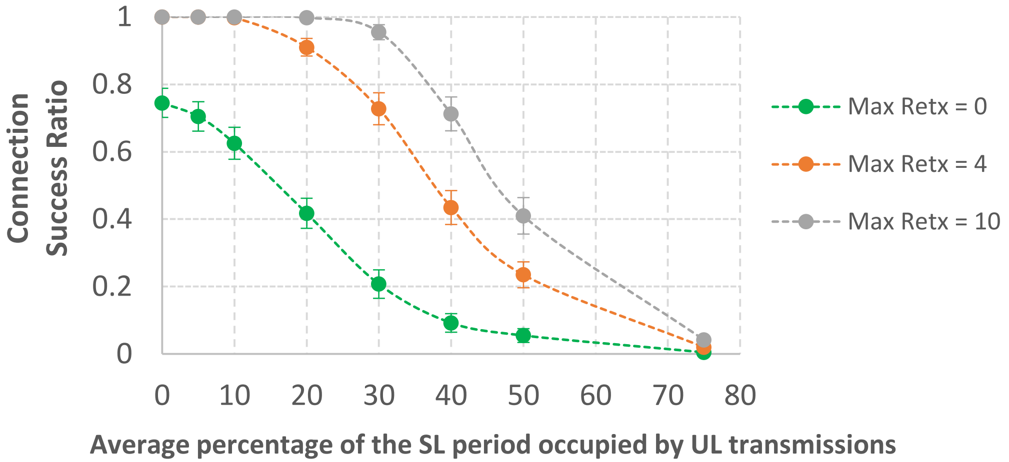
		SL period length	
		0.04 s	0.32 s
Number of periods	5	0.20 s	1.60 s
	10	0.40 s	3.20 s
	20	0.80 s	6.40 s
	30	1.20 s	9.60 s

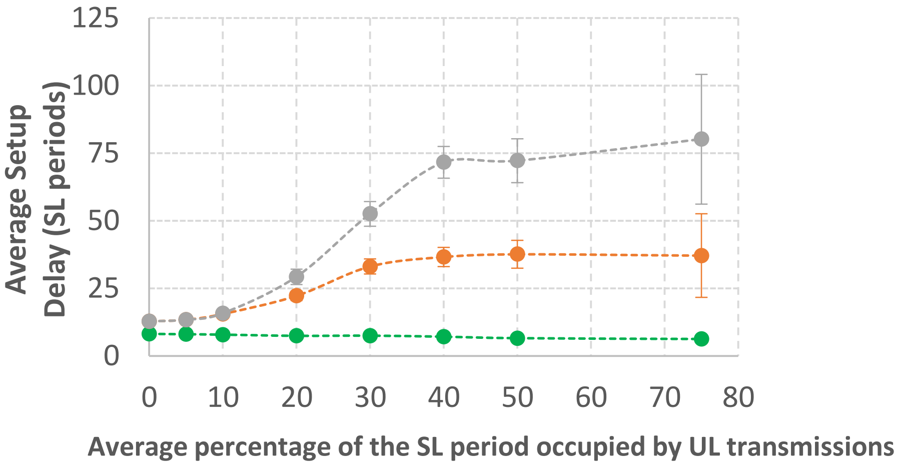
- The configuration of timer T4100 depends on the number of Remote UEs the Relay UE is communicating with in the Sidelink
- Retransmissions increase reliability but also latency

➔ Deployment must be considered when configuring protocols

Impact of Uplink Occupancy

4 Remote UEs and T4100 = 16 SL periods





Results with UL traffic and no scheduling coordination between UL and SL

Connection time		SL period length	
		0.04 s	0.32 s
Number of periods	10	0.40 s	3.20 s
	25	1.00 s	8.00 s
	50	2.00 s	16.00 s
	75	3.00 s	24.00 s

- Frequent uplink transmissions lower the sidelink connection reliability
- Increasing the number of retransmission can mitigate the loss but cause significant delays

➔ Coordination between uplink and sidelink resource allocation is needed

Relay Communication

What are the effects on application performance?
Will the user experience be affected?

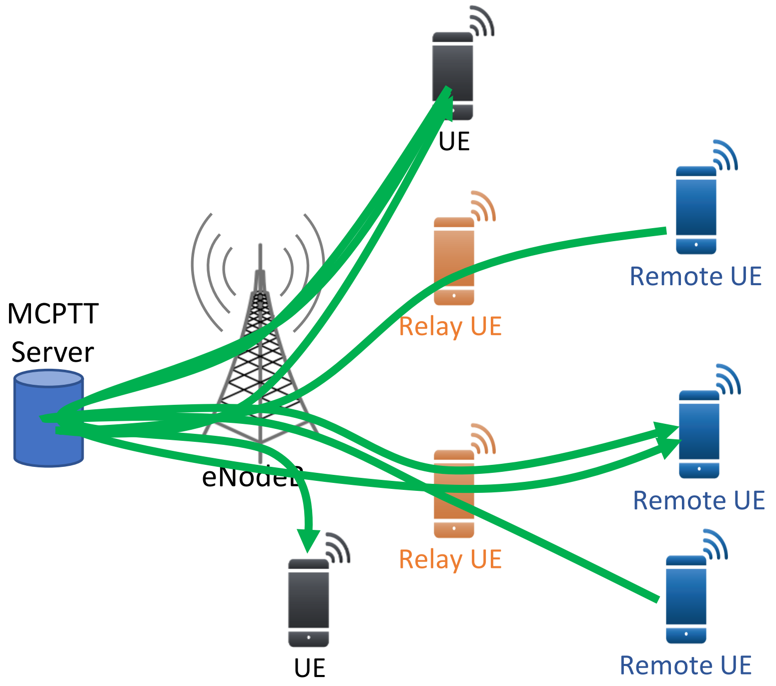
Mission Critical Push-to-Talk (MCPTT)
Performance Requirements

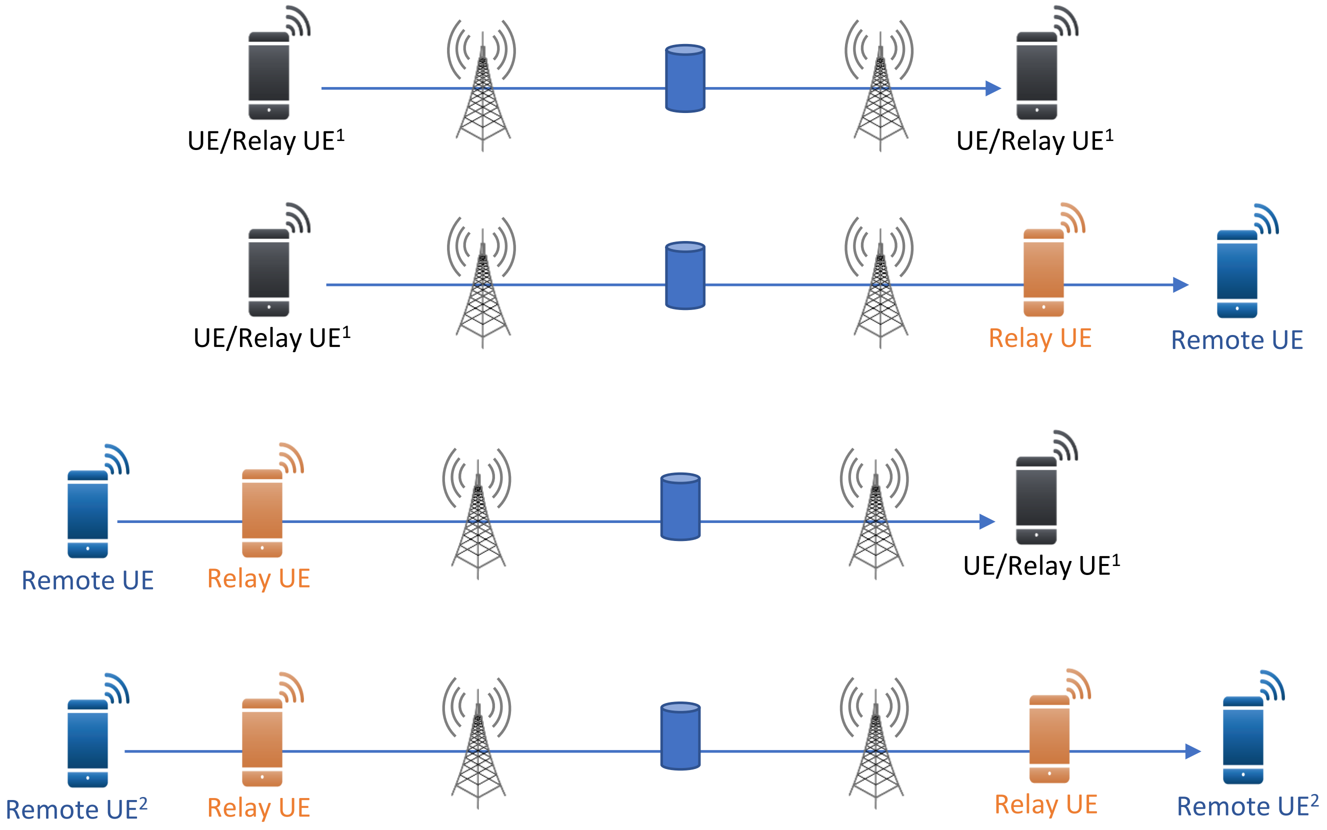
- 3GPP defines performance requirements for on network (TS 22.179)
  - **MCPTT Access time** (KPI 1) **less than 300 ms** for 95 % of all MCPTT Request.
  - **End-to-end MCPTT Access time** (KPI 2) **less than 1000 ms**
    - For users under coverage of the same network when the MCPTT Group call has not been established prior to the initiation of the MCPTT Request.
  - **Mouth-to-ear latency** (KPI 3) that is **less than 300 ms** for 95 % of all voice bursts.
  - Assumes negligible backhaul delay, max 70 % load, no transcoding

➔Can the same requirements be met when connected to a UE-to-Network relay?

Relay Communication Paths

Scenarios with group communication

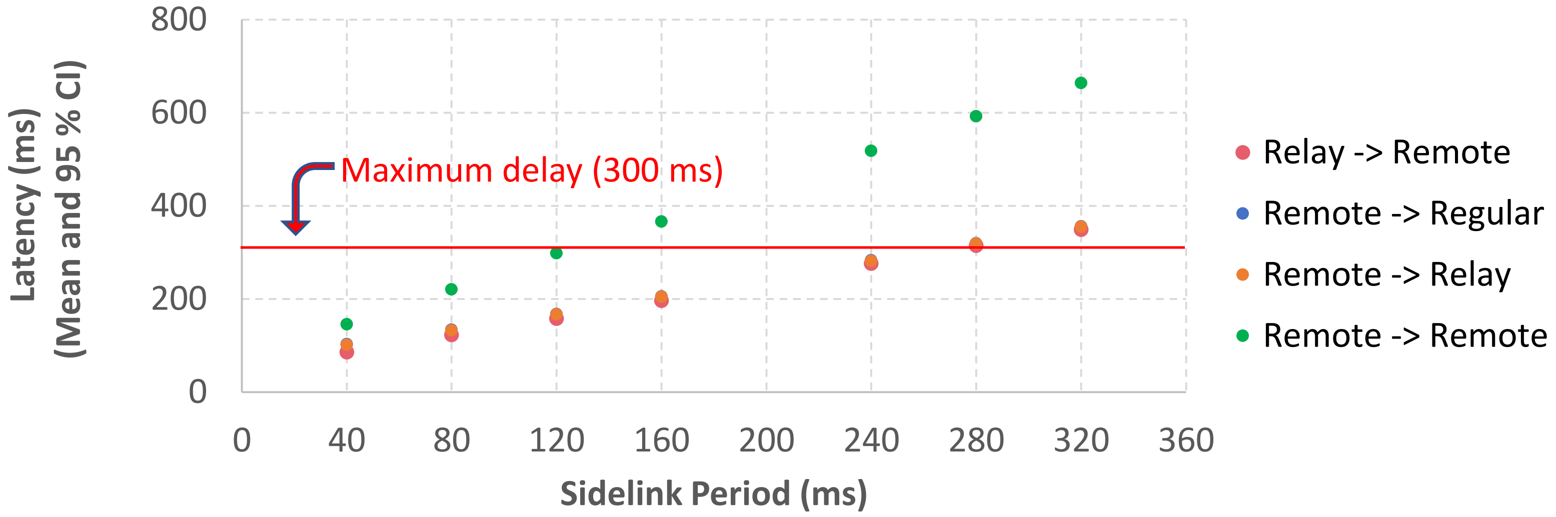




[1]While relay UEs are in coverage, delays to/from a relay UE might differ from that of a non-relay UE

[2]Performance will change whether the transmitter and receiver remote UEs are connected to the same relay or not

Impact of Sidelink on Mouth-to-Ear Latency



- Performance shown are for a network where only the media traffic is carried (no other load on the network)
- When a Remote UE is involved, the higher the sidelink period, the larger the latency

➔ Sidelink period configuration must be configured considering end-to-end packet delay requirements

Lessons Learned

- UE-to-Network relays can help maintain connectivity for UEs losing coverage while in proximity of other UEs that are still in coverage
- Preliminary results show that performance are sensitive to several factors including:
  - Number of devices that can act as Relay UEs
  - Number of devices communicating with the Relay UEs
  - Sidelink configuration
  - Traffic load
- Users may notice some service degradation under certain conditions compared to on-network
- Our work will provide guidelines to configure the resources allocated to D2D and the protocol configurations to ensure proper operations

Areas for Future Investigation

- Relay activation
  - Algorithms to detect when/where a relay might be needed
- Interference mitigation
  - Reduce collisions between uplink and sidelink
- Impact on energy consumption
  - Quantify additional energy cost to the relay nodes
- Protocol configuration
  - Guidelines for configuring timers and maximum number of retransmissions (i.e., keep alive, failure recovery)
